Executive Summary

The Ex-HMAS Adelaide was gifted from the Australian to the NSW Government for the specific purpose of scuttling the ship as an artificial dive reef off the Central Coast of NSW. In accordance with the Artificial Reef (Sea dumping) permit, the Department of Primary Industries - Catchments and Lands, must implement a Long Term Monitoring and Management Plan (LTMMP) prepared by Worley Parsons in March 2011.

The LTMMP covers environmental and structural monitoring for the first five years post-scuttling and forms the basis for ongoing monitoring and maintenance over the operational life of the vessel as a dive site, which is estimated to be 40 years. Part of the LTMMP involves the monitoring of marine sediments in and around the ship to examine how metal corrosion and degradation of protective paint layers over time may impact on the surrounding marine environment and benthic biota.

Sediments were collected by a benthic ponar grab deployed from a vessel at reference and monitoring locations. Sediments were also collected by commercially qualified (ADAS Part 3) divers (supplied by McClelland Diving Services) at three locations within the hull of the ship. As per the requirements of the LTMMP, sediment samples were tested for aluminium, iron, chromium, copper, lead, nickel and zinc. Sediments collected from the hull of the ship were tested for lead only.

The survey found that concentrations of metals in sediment samples at monitoring and reference sites were well below the Australian and New Zealand Fresh and Marine Water Quality Guidelines (ANZECC/ARMCANZ 2000) ISQG (Interim Sediment Quality Guideline) lower trigger values (for metals which guidelines are established). Metal concentrations at monitoring sites were very similar to those at reference sites. Comparison of metal concentrations from the current survey (six months post-scuttling) with earlier surveys, also showed that metal concentrations were generally lower for the current survey than at the time of the baseline survey and one month post-scuttling. Lead concentrations found in all three samples collected within the ship's hull (current survey only) were less than 5 mg/kg which was well below the lower ISQG trigger value of 50 mg/kg.

The results of the sediment quality survey indicate that six months on from the scuttling of the Ex-HMAS Adelaide, there has been no appreciable increase in the concentrations of the metals tested in marine sediments adjacent to the ship. Rather, for many of the metals analysed (aluminium, chromium, iron, nickel and zinc), concentrations were lower than in previous surveys. Concentrations of copper and lead were similar for all surveys. Testing of sediments which have accumulated within the hull of the ship did not indicate SIGNIFICANT lead contamination.

Based on these findings, impact to the marine environment and associated benthic biota as a result of metal corrosion and/or degradation of paint layers from the Ex-HMAS is considered unlikely.

Glossary

Artificial Reef	A structure or formation placed on the seabed for the purpose of increasing or concentrating populations of marine plants and animals or for the purpose of being used in human recreational activities.
ANZECC/ARMCANZ	Australian and New Zealand Environment Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand.
Bioaccumulation	The accumulation of substances, such as pesticides or heavy metals in an organism. Bioaccumulation occurs when an organism absorbs a toxic substance at a rate greater than that at which the substance is eliminated.
Biomagnification	Where animals feeding on bioaccumulators have a diet enriched with these substances. If unable to excrete them they aquire an even greater body burden of the substance.
DSEWPaC	Department of Sustainability, Environment, Water, Population and Communities.
EP&A Act	Environmental Planning & Assessment Act 1979.
LAT	Lowest Astronomical Tide.
LTMMP	Long Term Management and Monitoring Plan.

1 Introduction

1.1 Background and Aims

Cardno (NSW/ACT) trading as Cardno Ecology Lab Pty Ltd was commissioned by the NSW Department of Primary Industries – Catchments and Lands (DPI Catchments and lands), to undertake the post-scuttling environmental monitoring for the Ex-HMAS Adelaide artificial reef and dive site.

The Ex-HMAS Adelaide was gifted from the Australian to the NSW Government for the specific purpose of scuttling the ship as an artificial reef off the Central Coast of NSW. A comprehensive environmental assessment was undertaken for the project in accordance with state and federal environmental legislation. This included approval under the NSW *Environmental Planning and Assessment Act 1979* (EP&A Act) and obtaining an Artificial Reef (or Sea Dumping) Permit issued under the *Environment Protection (Sea Dumping) Act 1981* from the federal Department of Sustainability, Environment, Water, Population and Communities (DSEWPaC).

Sea Dumping Permits ensure that appropriate sites are selected, materials are suitable and appropriately prepared, that there are no significant adverse impacts on the marine environment and that the reef does not pose a danger to marine users. A condition of the Permit is that DPI Catchments and Lands must implement the proposed Long Term Monitoring and Management Plan (LTMMP) prepared by Worley Parsons in March 2011.

The LTMMP covers environmental and structural monitoring for the first five years post-scuttling and forms the basis for ongoing monitoring and maintenance over the operational life of the vessel as a dive site, which is estimated to be 40 years. The frequency of monitoring and the methodologies used will be reviewed periodically during the life of the Plan. The scope of work to be carried out by Cardno Ecology Lab is for a two year period post-scuttling, which follows on from initial baseline investigations carried out by Worley Parsons in April/May 2011. It includes the following environmental monitoring components:

- Reef communities;
- Sediment quality; and
- Bioaccumulation studies.

This Progress Report outlines the methodology and findings for the first of two sediment quality surveys. These surveys are to be carried out six and 18 months post-scuttling. Sediment quality will then be analysed again at 60 months post-scuttling. Annual sampling and analysis is not proposed.

The aim of the sediment quality monitoring survey, as outlined in the LTMMP, is to gain an understanding of how metal corrosion and degradation of paint layers is influencing/impacting on the marine environment and whether benthic organisms are likely to be affected by metal enrichment. The LTMMP stipulates that sediment testing is carried out for the following metals:

- Aluminium;
- Iron;
- Chromium;
- Copper;
- Lead;
- Nickel; and
- Zinc.

Sediment quality results are to be compared with ANZECC/ARMCANZ (2000) Guidelines and previous results for reference sites. As required by the monitoring condition set by the Administrative Appeals Tribunal, sediment from two sites within the hull is also to be sampled and analysed for lead to measure any changes in sediment lead concentrations over time. The location of the monitoring sites shall be in the bottom centre of the Laundry (compartment number 4-140-0-Q); and Auxiliary Machinery Room Number 3 (compartment number 5-292-0-L).

This progress report outlines the following:

- Description of sampling dates, times, weather conditions and tidal height;
- Description of the methods used to retrieve sediment samples;
- Results and interpretation of laboratory analyses;
- Discussion of findings; and

Reports of any condition or occurrence that may influence results of the study.

1.2 Study Site and Nature of Contaminants

The Ex-HMAS Adelaide artificial reef and dive site is located within Bulbararing Bay, approximately 1.87 km offshore from Avoca Beach. The ship lies at a depth of approximately 32 m to 34 m of water at Lowest Astronomical Tide (LAT) on top of a relatively flat, sandy substratum. There is a minimum of 6 m of sand

overlying bedrock. The vessel is orientated with the bow facing into the prevailing ESE swell direction (**Figure 1**).

The ship is 138.1 m in length, with a beam of 14.3 m and an original displacement of 4,200 tonnes. The hull is made of steel and the superstructure of aluminium alloy. Heights are approximately 12 m to the main deck, 18 m to the bridge, 24 m to the top of the foremast (the mast closest to the bow), and 39 m to the top of the mainmast (NSW Government 2011). The ship was prepared for scuttling by McMahon's Services. This involved the removal of the main mast structures for safety and navigation reasons and stripping of machinery, hatches and any items that could pose a risk to divers or the environment. Potential contaminants such as fuels, oils, heavy metals, batteries and electrical items containing polychlorinated biphenols (PCBs) were removed. Diver access holes have been cut into the sides of the hull, floors and ceilings to allow extra vertical access between decks and also to allow light to penetrate. Further holes were also made to allow air to escape during the scuttling process (NSW Government 2011).

The Ex-HMAS Adelaide was prepared to meet DSEWPaC standards which were specified during the months of preparation prior to scuttling. DSEWPaC had conducted a series of inspections to confirm that its detailed requirements were achieved. The original clean-up process included removing loose or flaking paint in accordance with DSEWPaC's requirements. A total of 110 paint locations were then tested from representative locations across the ship, confirming the presence of lead primer at some locations on the steel lower decks of the ship. The paint at other locations tested had yellow primer, red oxide, white topcoat and grey topcoat which did not contain lead. The use of lead-based primer is only relevant to the internal steel hull and lower decks of the ship where it was used for corrosion protection, as the superstructure is constructed of aluminium.

Environmental risk experts concluded that the risks to the environment and human health from the presence of lead-based primer are negligible because the lead primer used is in the form of lead tetroxide, which is very insoluble so there would be minimal leaching. The lead is also in a form that has low bioavailability, little potential for bioaccumulation, and does not biomagnify. Risks due to copper in the anti-fouling paint are not a significant concern because the coating is designed to leach as part of its protective process and the leaching rate declines after the first six months. Because of this declining rate, the Navy's standard practice is to apply a new coating every five years and the last coating was applied to the Adelaide seven years ago, so it is therefore near the end of its useful life, thus reducing the amount of copper remaining that could be released into the marine environment.

1.3 Previous Studies

Prior to the current study, sediment was collected and analysed for metal contaminants before the scuttling of the Ex-HMAS (baseline survey) and also one month post-scuttling.

During the baseline survey (Worley Parsons 2009) marine sediments were collected from three sites in the approximate location in which the Ex-HMAS Adelaide would be scuttled. Concentrations of all metals in the baseline survey were less than their respective ANZECC / ARMCANZ (2000) ISQG-Low values (where these had been established). One month post-scuttling, the concentrations of metals in sediment at all reference and impact sites were below the ISQG-Low values, indicating that there is a low risk that any adverse biological effects will occur to marine organisms living within the sediments surrounding the Ex-HMAS Adelaide (Worley Parsons 2011). Mean metal concentrations in sediments obtained during the previous two surveys were very similar.

2 Study Methods

2.1 Sampling Sites

Samples were collected from the same sites as those pre-determined by Worley Parsons in the earlier (one month post-scuttling survey). These included a total of nine samples with three reference locations (S2, S3 and S6) and six monitoring locations (I1, I2, I3, I4, I5 and I6). For continuity, the same location ID's have been used as the previous survey. Locations and GPS positions of the nine sampling locations are given in **Table 1** and **Figure 2**. Three samples were also collected from the bow, midship and stern sections from within the hull of the ship for analyses of lead content (**Figure 3**). Samples had not been collected from these locations in previous surveys as no sediment had accumulated within the hull at that time.

Monitoring Site - I1	33°27.843'	151°27.428'
Monitoring Site- I2	33°27.849'	151°27.479'
Monitoring Site - I3	33°27.864'	151°27.522'
Monitoring Site - I4	33°27.942'	151°27.449'
Monitoring Site - I5	33°27.921'	151°27.416'
Monitoring Site - I6	33°27.897'	151°27.381'

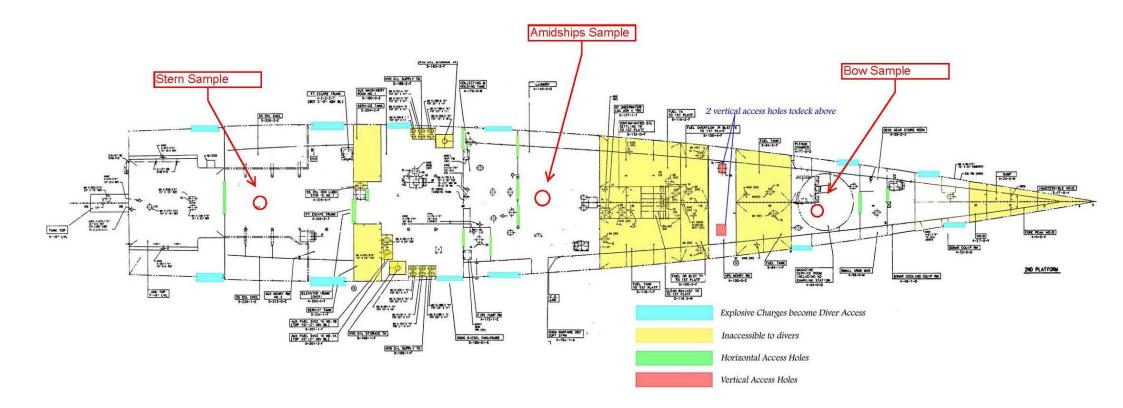

Figure 3: Locations of Sediment Sampling Sites within the Hull of the Ex-HMAS Adelaide. Samples were collected by divers from McClelland's Diving Services on 06 October 2011.

2.2 Sampling Methodology

2.2.1 Adjacent Sediments

Sediment samples were collected by deploying a Ponar benthic grab from a boat. The sampler collects approximately 2 L of sediment. At each site, co-ordinates were recorded using GPS (accurate to < 5 m). Approximately 500 g of sediment was extracted from each grab, transferred into a polyurethane zip-lock bag and chilled in an esky. After each sample was collected, the sieve was inverted and rinsed with a jet of water to avoid cross-contamination of samples. Each sample was clearly labelled internally and externally, with the project details, time, date, location, site and replicate number. Samples were refrigerated at 4°C overnight then sent by courier to ALS laboratories (an NATA accredited laboratory), Sydney for processing.

2.2.2 Sediments within the Hull

Samples were collected by commercially qualified (ADAS Part 3) divers and sealed into zip-lock polyurethane bags, placed inside a second bag and then placed in an esky. Samples were refrigerated at 4°C overnight, then sent by courier to ALS laboratories, Sydney (an NATA accredited laboratory) for processing the following day. These samples were analysed for lead concentration only, as per the requirements of the LTMMP.

2.2.3 Laboratory Methods

Sediment samples were tested for trace metals aluminium (AI), iron (Fe), chromium (Cr), copper (Cu), lead (Pb), nickel (Ni) and zinc (Zn) against NODG (National Ocean Disposal Guideline for Dredged Material 2002) and ANZECC/ARMCANZ (2000) Interim Sediment Quality Guidelines.

Sediment samples were prepared by 'Hot Block Digest' for metals in soils, sediments and sludges and tumbler extraction of solids/sample clean up. Moisture content was calculated by a gravimetric procedure based on weight loss over a 12 hour drying period at 103 – 105°C. Total metals in sediments were calculated by the ICPMS (Inductively Coupled Plasma Mass Spectrometry) technique which uses argon plasma to ionise selected elements. Ions are then passed into a high vacuum mass spectrometer, which separates the analytes based on their distinct mass to charge ratios prior to their measurement by a discrete dynode ion detector. FIMS (Flow Injunction Mercury System) was used to test low level mercury content whereby an atomic absorption technique is used followed by an appropriate acid digestion.

2.3 Analyses

Sediment concentrations were reported as means with standard deviations from the mean. Concentrations of heavy metals found within sediment samples at all sites were compared to Australian and New Zealand Fresh and Marine Water Quality Guidelines (ANZECC/ARMCANZ 2000). The recommended guideline values are tabulated as Interim Sediment Quality Guidelines (ISQG) where low and high ISQG values correspond to low and medium effects ranges (ANZECC and ARMCANZ 2000).

Metal concentrations at monitoring sites (I1 - I6) were compared with concentrations at reference locations (S2, S3 and S6) and also compared among survey times: baseline, one month post-scuttling and the current survey (6 months post-scuttling).

2.4 Assumptions and Limitations

Location S2 is not considered to be appropriate as a reference location due to its close proximity to the ship and other monitoring locations. This should therefore be treated with caution when considering the overall results.

3 Results

Sediment samples from monitoring locations in the vicinity of the Ex-HMAS Adelaide and at reference location were collected on 20th October 2011. Sea conditions were calm with a NNW breeze in the morning changing to a moderate NE breeze in the afternoon (BOM 2011). The tide was low (0.7 m) in the morning rising to a high of 1.45 in the afternoon (14:45).

Concentrations of metals in sediment samples at monitoring and reference sites were well below the ANZECC/ARMCANZ ISQG lower trigger values (for metals which guidelines are established). Metal concentrations at monitoring sites were also very similar to those at control sites (**Table 2**).

Comparison of metal concentrations from the current survey (six months post-scuttling) with earlier (one month post-scuttling and baseline) surveys show that metal concentrations in the current survey were generally lower than at the time of the baseline survey and one month post-scuttling (**Table 3**).

Sediments from within the ship's hull were collected on 5 October 2011 by a team of commercially qualified (ADAS Part 3) divers supplied by McClelland Diving Services. Sea conditions were calm and fine with a light offshore (NNW) breeze (BOM 2011). The tide was low in the morning (0.6 m) pushing to a high of 1.5 m in the afternoon (16:05). Lead concentrations found in all three samples were less than 5 mg/kg which was well below the lower ISQG trigger value of 50 mg/kg.

 Table 3: Mean Metal Concentrations (mg/kg) in Marine Sediments Collected during Baseline and

 Monitoring Surveys One and Six Months Post-Scuttling of the Ex-HMAS Adelaide.

	Baseline	Monitoring Sites					
Metal	Baseline Mean (mg/kg)	1 Month Post-Scuttling Mean (mg/kg)	6 Months Post-scuttling Mean (mg/kg)				
Aluminium	1183	1183	180				
Chromium	7.6	7.1	1.5				
Copper	1.4	2.0	2.1				
Iron	9603	9567	1205				
Nickel	2.5	2.4	<1.0				
Lead	3.5	3.3	2.0				
Zinc	10.2	10.3	2.7				

4 Discussion

The results of the sediment quality survey indicate that six months post-scuttling of the Ex-HMAS Adelaide there has been no appreciable increase in the concentrations of the metals tested (aluminium, chromium, copper, iron, nickel, lead and zinc) in marine sediments adjacent to the ship. Rather, for many of the metals analysed (aluminium, chromium, iron, nickel and zinc), concentrations were lower than in previous surveys. Concentrations of copper and lead were similar among all surveys. Testing of sediments which have accumulated within the hull of the ship did not indicate significant lead contamination.

Based on these findings, impact to the marine environment and associated benthic biota as a result of metal corrosion and/or degradation of paint layers from the Ex-HMAS is considered unlikely.

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insuffient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society. LOR = Limit of reporting

^ = This result is computed from individual analyte detections at or above the level of reporting

- Analytical Results

ACCREDITATION

Environmental Division Sydney Part of the ALS Laboratory Group 277-289 Woodpark Road Smithfield NSW Australia 2164 Tel. +61-2-8784 8555 Fax. +61-2-8784 8500 www.alsglobal.com A Campbell Brothers Limited Company

General Comments

The analytical procedures used by the Environmental Division have been developed from established internationally recognized procedures such as those published by the USEPA, APHA, AS and NEPM. In house developed procedures are employed in the absence of documented standards or by client request.

Where moisture determination has been performed, results are reported on a dry weight basis.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insuffient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

When sampling time information is not provided by the client, sampling dates are shown without a time component. In these instances, the time component has been assumed by the laboratory for processing purposes.

Key : CAS Number = CAS registry number from database maintained by Chemical Abstracts Services. The Chemical Abstracts Service is a division of the American Chemical Society. LOR = Limit of reporting

^ = This result is computed from individual analyte detections at or above the level of reporting
